Problem Statement
- Existing TMs exhibit high abort rates
- Pessimistic conflict detection
- Limits concurrency and performance

Snapshot Isolation (SI)
- Transactions obtain a memory snapshot at TX_START
- All reads target the consistent snapshot
- Writes are buffered until TX_COMMIT
- Validation only checks for write-write conflicts

Properties of SI
- SI transactions do not abort on read-write conflicts
- Read only transactions always commit
- Requires multiversion concurrency control

Indirection Layer

SI-TM Avoids Read-Write Conflicts

SI-TM Challenges
- How to generate snapshots efficiently?
- How to address the write skew anomaly?

Multiversion Memory (MVM)
- Immutability - Data is never updated in place
- Instead, updates are supported through copy-on-write
- Multiple versions can coexist in the same memory space
- Disambiguate versions through timestamps
- Utilize indirection layer to map addresses to data versions

Methodology
- Cycle accurate simulator (Zsim)
- Detailed functional, timing models
- 2-phase locking baseline
- Conflict serializability baseline

Evaluation
- 3 Microbenchmarks
- STAMP suite
- 8 - 32 threads
- Up to 300x fewer aborts
- Up to 20x higher performance

Abort Rate Reduction
